#### 1. Introduction

We are interested in the constrained minimization of a large sum of nonconvex functions defined as  $\min_{\theta \in \Theta} \left[ f(\theta) \triangleq \sum_{i=1}^{N} f_i(\theta) \right]$  where  $\Theta$  is a convex subset of  $\mathbb{R}^p$  and or all  $i \in [N]$ ,  $f_i : \mathbb{R}^p \to \mathbb{R}$  are continuously differentiable, bounded from below and possibly nonconvex. In this paper, we solve this minimization problem using a Majorization-Minimization (MM) algorithm (Lange, 2016; Razaviyayn et al., 2013) which works by finding iteratively a surrogate function that majorizes the objective function. MM algorithms are very popular in machine learning and computational statistics (Lange, 2016). Examples include proximal gradient algorithms (Parikh and Boyd, 2014; Mishchenko et al., 2018), the Expectation-Maximization (EM) algorithm (McLachlan and Krishnan, 2007) and some variational inference methods (Wainwright and Jordan, 2008). When the objective function is a finite-sum, (Mairal, 2015) developed an incremental MM scheme, called MISO, taking advantage of the finite-sum structure with a cost per iteration that is independent of N. However, the MISO framework rests upon the computation of tractable surrogates such as quadratic functions. Yet, in many cases, those surrogates are intractable and need to be approximated. This is the case in particular in Bayesian Deep Learning (Ghahramani, 2015; Ranganath et al., 2014; Kingma and Welling, 2013). Ultimately, MISO convergence guarantees can not be applied on those cases where approximation of surrogates are used; they often rely on Robbins and Monro (Robbins and Monro, 1951) convergence results for stochastic optimization.

In this contribution, we propose an incremental MM algorithm, called MISSO (Minimization by Incremental Stochastic Surrogate Optimization) when the natural surrogate functions are intractable and should be approximated, for example by Monte Carlo integration, and provide asymptotic convergence guarantees.

# 2. Minimization by Incremental Stochastic Surrogate Optimization (MISSO)

**M** 1. For  $i \in [N]$ ,  $f_i$  is continuously differentiable on a neighborhood  $\mathcal{T}(\Theta)$  of  $\Theta$  and is bounded from below

For any  $\theta \in \Theta$  and  $i \in [N]$ , we say, following (Mairal, 2015) that a function  $f_{i,\theta} : \mathbb{R}^p \to \mathbb{R}$  is a surrogate of  $f_i$  at  $\theta$  if the function  $\vartheta \to f_{i,\theta}(\vartheta)$  is continuously differentiable on  $\mathcal{T}(\Theta)$ ,  $f_{i,\theta}(\vartheta) \geq f_i(\vartheta)$ ,  $f_{i,\theta}(\theta) = f_i(\theta)$  and  $\nabla f_{i,\theta}(\vartheta)\Big|_{\vartheta=\theta} = \nabla f_i(\vartheta)\Big|_{\vartheta=\theta}$ .

**M 2.** For  $i \in [N]$ ,  $h_{i,\theta} \triangleq f_{i,\theta} - f_i$  is L-smooth, i.e. for all  $(\theta, \vartheta, \vartheta') \in \Theta^3$ :  $|\nabla h_{i,\theta}(\vartheta) - \nabla h_{i,\theta}(\vartheta')| \leq L|\vartheta - \vartheta'|$ 

We introduce an incremental scheme to deal with the case of intractable surrogate functions. We assume that the surrogate can be expressed as an integral over a set of latent variables, denoted  $z = (z_i \in \mathsf{Z}_i, i \in \llbracket N \rrbracket) \in \mathsf{Z}$  where  $\mathsf{Z} = \times_{i=1}^N \mathsf{Z}_i$  with  $\mathsf{Z}_i$  a subset of  $\mathbb{R}^{m_i}$ . For all  $i \in \llbracket N \rrbracket$ , let  $\mu_i$  be a  $\sigma$ -finite measure on the Borel  $\sigma$ -algebra  $\mathcal{Z}_i = \mathcal{B}(\mathsf{Z}_i)$ ,  $\mathcal{P}_i = \{p_i(z_i,\theta); \theta \in \Theta\}$  be a family of probability densities with respect to  $\mu_i$ , and  $r_{i,\theta} : \mathsf{Z}_i \times \Theta \to \mathbb{R}$  be functions such that:

$$f_{i,\theta}(\vartheta) \triangleq \int_{\mathsf{Z}_i} r_{i,\theta}(z_i,\vartheta) p_i(z_i,\theta) \mu_i(\mathrm{d}z_i) \quad \text{for all } (\theta,\vartheta) \in \Theta^2.$$
 (1)

Our scheme is based on the computation, at each iteration, of stochastic surrogate functions for a mini-batch of components. For  $i \in [N]$ , the stochastic surrogate function, noted  $\hat{f}_{i,\theta}^M(\vartheta)$  is a Monte Carlo approximation of the surrogate function  $f_{i,\theta}(\vartheta)$  defined by (1) such that:

$$\hat{f}_{i,\theta}^{M}(\vartheta) \triangleq \frac{1}{M} \sum_{m=0}^{M-1} r_{i,\theta}(z_i^m, \vartheta) \quad \text{for all } (\theta, \vartheta) \in \Theta^2$$
 (2)

where  $\{z_i^m\}_{m=0}^{M-1}$  is a Monte Carlo batch. The MISSO algorithm reads:

#### Algorithm 1 MISSO algorithm

**Initialization**: given an initial estimate  $\theta^0$ , compute  $\vartheta \to \hat{f}_{i,\theta^0}^{M_0}(\vartheta)$  defined by (2) for  $i \in [N]$ . **Iteration k**: given the current estimate  $\theta^{k-1}$ :

- 1. Pick a set  $I_k$  uniformly on  $\{A \subset [\![N]\!], \operatorname{card}(A) = p\}$
- 2. For all  $i \in I_k$ , sample a Monte Carlo batch  $\{z_i^{k,m}\}_{m=0}^{M_k-1}$  from  $p_i(z_i, \theta^{k-1})$  and compute  $\theta \to \hat{f}_{i,\theta^{k-1}}^{M_k}(\theta)$  defined by (2)
- 3. Set  $\theta^k \in \arg\min_{\vartheta \in \Theta} \sum_{i=1}^N \hat{a}_i^k(\vartheta)$  where  $\hat{a}_i^k(\vartheta)$  are defined recursively as follows:  $\hat{a}_i^k(\vartheta) \triangleq \hat{f}_{i,\theta^{k-1}}^{M_k}(\vartheta)$  if  $i \in I_k$  and  $\hat{a}_i^{k-1}(\vartheta)$  otherwise

Whether we use MCMC or direct simulation, we need to control the supremum norm of the fluctuations of the Monte Carlo approximation. Let  $i \in [N]$ ,  $\{j_i(z_i, \vartheta), z_i \in \mathsf{Z}_i, \vartheta \in \Theta\}$  be a family of measurable functions. We define:

$$C_{i}(j_{i}) \triangleq \sup_{\theta \in \Theta} \sup_{M>0} M^{-1/2} \mathbb{E}_{i,\theta}^{M} \left[ \sup_{\theta \in \Theta} \left| \sum_{m=0}^{M-1} \left\{ j_{i}(z_{i}^{m}, \theta) - \int_{\mathsf{Z}_{i}} j_{i}(z_{i}, \theta) p_{i}(z_{i}, \theta) \mu_{i}(\mathrm{d}z_{i}) \right\} \right| \right]$$
(3)

where we denote by  $\mathbb{E}_{i,\theta}^{M}$  is the expectation of the samples  $\{z_{i}^{m}\}_{m=0}^{M-1}$ 

- **M 3.** For all  $i \in [N]$  and  $\theta \in \Theta$ :  $\lim_{k \to \infty} C_i(r_{i,\theta}) < \infty$  and  $\lim_{k \to \infty} C_i(\nabla r_{i,\theta}) < \infty$ .
- **M** 4.  $\{M_k\}_{k\geq 0}$  is a non deacreasing sequence of integers which satisfies  $\sum_{k=0}^{\infty} M_k^{-1/2} < \infty$ .

**Theorem 1.** Assume M1-M4. Let  $(\theta^k)_{k\geq 1}$  be a sequence generated from  $\theta^0 \in \Theta$  by the iterative application described by Algorithm 1. Then:

(i)  $(f(\theta^k))_{k\geq 1}$  converges almost surely and  $(\theta^k)_{k\geq 1}$  satisfies the Asymptotic Stationary Point Condition of (Mairal, 2015).

**Proof** The proof is postponed to the supplementary material.

# 3. Incremental Variational Inference for Bayesian Deep Learning

Let  $x = (x_i, i \in [\![N]\!])$  and  $y = (y_i, i \in [\![N]\!])$  be i.i.d. input-output pairs and w be a global latent variable taking values in W a subset of  $\mathbb{R}^J$ . A natural decomposition of the joint distribution is  $p(y, x, w) = p(w) \prod_{i=1}^N p_i(y_i|x_i, w)$ . The goal is to calculate the posterior distribution p(w|y, x). The classical variational inference problem boils down to minimizing the following Kullback Leibler (KL) divergence:

$$\theta^* = \arg\min_{\theta \in \Theta} \text{KL}(q(w; \theta) \parallel p(w|y, x)) = \arg\min_{\theta \in \Theta} f(\theta) = \arg\min_{\theta \in \Theta} \sum_{i=1}^{N} f_i(\theta)$$
 (4)

where  $q(w;\theta)$  belongs to the multivariate Gaussian family and  $f_i$  is defined as:

$$f_i(\theta) \triangleq -\int_{\mathsf{W}} \log p_i(y_i|x_i, w) q(w; \theta) dw + \frac{1}{N} \operatorname{KL}(q(w; \theta) \parallel p(w)) = l_i(\theta) + d(\theta)$$
 (5)

Even though this procedure makes inference analytical for a large class of models, it still lacks in many ways. This technique does not scale to large data since it requires calculations over the entire dataset and the approach does not adapt to complex models (models in which this last integral cannot be evaluated analytically) such as Bayesian neural networks (Neal, 2012; Gal, 2016). The former challenge is tackled by (Hoffman et al., 2013) with the Stochastic Variational Inference algorithm and the latter is addressed by (Kucukelbir et al., 2017; Blundell et al., 2015) where the intractable expectation  $l_i$  in (5) is integrated by Monte Carlo. We perform this optimization step using our framework MISSO with the following quadratic surrogate at  $\theta \in \Theta$ :

$$f_{i,\theta}(\vartheta) \triangleq f_i(\theta) + \nabla f_i(\theta)^\top (\vartheta - \theta) + \frac{L}{2} \|\vartheta - \theta\|_2^2 \quad \text{for all } \vartheta \in \Theta \text{ and } i \in [N]$$
 (6)

where  $\|\cdot\|_2$  is the  $\ell_2$ -norm and L is an upper bound of the spectral norm of the Hessian of  $f_i$  at  $\theta$ . Let  $t: \Theta \times \mathbb{R}^d \mapsto \mathbb{R}^d$  be a function and  $\phi$  be the density of the standard multivariate normal distribution  $\mathcal{N}_d(0, \mathrm{Id})$ . We assume that for all  $\theta \in \Theta$ , the distribution of the random vector  $w = t(\theta, \epsilon)$ , where  $\epsilon \sim \mathcal{N}_d(0, \mathrm{Id})$ , has a density  $q(\cdot, \theta)$ . Then, following (Blundell et al., 2015, Proposition 1),  $\nabla l_i(\theta)$  is computed as:

$$\nabla l_i(\theta) = -\nabla \int_{\mathsf{W}} \log p_i(y_i|x_i, w) q(w; \theta) dw = -\int_{\mathsf{W}} J(\theta, z_i) \nabla \log p_i(y_i|x_i, t(\theta, z_i)) \phi(z_i) \mu_i(dz_i)$$
(7)

where for each for  $i \in [N]$ ,  $z_i \in \mathbb{R}^d$ ,  $J(\theta, z_i)$  is the Jacobian of the function  $t(\cdot, z_i)$  with respect to  $\theta$ .

Thus, at iteration k we get  $\theta^k = \frac{1}{N} \sum_{i=1}^N \theta^{\tau_{i,k}} - \frac{1}{2\gamma} \sum_{i=1}^N \{\hat{m}_i^k + \nabla d(\theta^{k-1})\}$  where  $\hat{m}_i^k = -\frac{1}{M_k} \sum_{m=0}^{M_k-1} J(\theta^{k-1}, z_i^{k,m}) \nabla_{\theta} \log p_i(y_i, x_i | t(\theta^{k-1}, z_i^{k,m}))$ , if  $i \in I_k$ , is the MC of (7) where  $\{z_i^{k,m}\}_{m=0}^{M_{k-1}}$  are i.i.d samples from  $\mathcal{N}_d(0, \mathrm{Id})$  and  $M_k$  is the size of the batch which might depend upon the iteration.

Numerical application: We apply variational inference for a 2-layer Bayesian neural network on the MNIST dataset (LeCun and Cortes, 2010) using our MISSO scheme. The training set is composed of  $N=60\,000$  handwritten digits,  $28\times28$  images, d=784. Our neural network is composed of an input layer with d=784 units, a single hidden layer of p=100 hyperbolic tangent units and a final softmax output layer with K=10 classes. We set  $p(w)=\mathcal{N}(0,\mathrm{Id})$  and  $p(y_i|x_i,w)=\mathrm{Softmax}(f(x_i,w))$  where f is the two layer model described above. We compare the convergence behaviors of the following state of the art optimization algorithms, using their vanilla implementations on TensorFlow (Abadi et al., 2015): the SGD (Kiefer and Wolfowitz, 1952), the ADAM (Kingma and Ba, 2014), the SAG (Le Roux et al., 2012) and the Momentum (Sutskever et al., 2013) algorithms versus our MISSO update with a constant learning rate of  $10^{-5}$ . Our estimator is computed using the Edward library (Tran et al., 2016). The batch size p is set to 1% and 10% of the training set as seen in Figure 1.

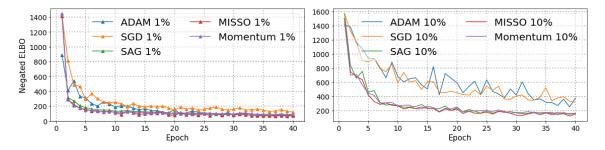

Figure 1: Convergence of the negated ELBO. Runs for two different mini-batch sizes.

# 4. Conclusion

In this paper, we have presented a unifying framework for minimization by incremental surrogate optimization when the surrogate functions are intractable and need to be approximated by MC integration. Our approach covers a large class of nonconvex optimization algorithms used in machine learning, such as mini-batch version of the Variational Inference algorithm. Non asymptotic convergence results for both convex and nonconvex objective functions can be obtained and will be reported in future works.

# 5. Supplementary material

#### Lemma 1

Let  $(V_k)_{k\geq 0}$  be a non negative sequence of random variables such that  $\mathbb{E}[V_0]<\infty$ . Let  $(X_k)_{k\geq 0}$  a non negative sequence of random variables and  $(E_k)_{k\geq 0}$  be a sequence of random variables such that  $\sum_{k=0}^{\infty} \mathbb{E}[|E_k|] < \infty$ . If for any  $k \geq 1$ :

$$V_k \le V_{k-1} - X_k + E_k \tag{8}$$

then:

- (i) for all  $k \geq 0$ ,  $\mathbb{E}[V_k] < \infty$  and the sequence  $(V_k)_{k \geq 0}$  converges a.s. to a finite limit  $V_\infty$ .
- (ii) the sequence  $(\mathbb{E}[V_k])_{k\geq 0}$  converges and  $\lim_{k\to\infty} \mathbb{E}[V_k] = \mathbb{E}[V_\infty]$ .
- (iii) the series  $\sum_{k=0}^{\infty} X_k$  converges almost surely and  $\sum_{k=0}^{\infty} \mathbb{E}[X_k] < \infty$ .

## Remark

Note that the result still holds if  $(V_k)_{k\geq 0}$  is a sequence of random variables which is bounded from below by a deterministic quantity  $M\in\mathbb{R}$ .

#### 5.1. Proof of Lemma 1

We first show that for all  $k \geq 0$ ,  $\mathbb{E}[V_k] < \infty$ . Note indeed that:

$$0 \le V_k \le V_0 - \sum_{j=1}^k X_j + \sum_{j=1}^k E_j \le V_0 + \sum_{j=1}^k E_j$$
(9)

showing that  $\mathbb{E}[V_k] \leq \mathbb{E}[V_0] + \mathbb{E}\left[\sum_{j=1}^k E_j\right] < \infty$ .

Since  $0 \le X_k \le V_{k-1} - V_k + \stackrel{\mathsf{L}}{E}_k$  we also obtain for all  $k \ge 0$ ,  $\mathbb{E}[X_k] < \infty$ . Moreover, since  $\mathbb{E}\left[\sum_{j=1}^{\infty} |E_j|\right] < \infty$ , the series  $\sum_{j=1}^{\infty} E_j$  converges a.s. We may therefore define:

$$W_k = V_k + \sum_{j=k+1}^{\infty} E_j \tag{10}$$

Note that  $\mathbb{E}[|W_k|] \leq \mathbb{E}[V_k] + \mathbb{E}\left[\sum_{j=k+1}^{\infty} |E_j|\right] < \infty$ . For all  $k \geq 1$ , we get:

$$W_{k} \leq V_{k-1} - X_{k} + \sum_{j=k}^{\infty} E_{j} \leq W_{k-1} - X_{k} \leq W_{k-1}$$

$$\mathbb{E}[W_{k}] < \mathbb{E}[W_{k-1}] - \mathbb{E}[X_{k}]$$
(11)

Hence the sequences  $(W_k)_{k\geq 0}$  and  $(\mathbb{E}[W_k])_{k\geq 0}$  are non increasing. Since for all  $k\geq 0$ ,  $W_k\geq -\sum_{j=1}^\infty |E_j|>-\infty$  and  $\mathbb{E}[W_k]\geq -\sum_{j=1}^\infty \mathbb{E}[|E_j|]>-\infty$ , the (random) sequence  $(W_k)_{k\geq 0}$  converges a.s. to a limit  $W_\infty$  and the (deterministic) sequence  $(\mathbb{E}[W_k])_{k\geq 0}$  converges to a limit  $w_\infty$ . Since  $|W_k|\leq V_0+\sum_{j=1}^\infty |E_j|$ , the Fatou lemma implies that:

$$\mathbb{E}[\liminf_{k \to \infty} |W_k|] = \mathbb{E}[|W_\infty|] \le \liminf_{k \to \infty} \mathbb{E}[|W_k|] \le \mathbb{E}[V_0] + \sum_{j=1}^{\infty} \mathbb{E}[|E_j|] < \infty$$
 (12)

showing that the random variable  $W_{\infty}$  is integrable.

In the sequel, set  $U_k \triangleq W_0 - W_k$ . By construction we have for all  $k \geq 0$ ,  $U_k \geq 0$ ,  $U_k \leq U_{k+1}$  and  $\mathbb{E}[U_k] \leq \mathbb{E}[|W_0|] + \mathbb{E}[|W_k|] < \infty$  and by the monotone convergence theorem, we get:

$$\lim_{k \to \infty} \mathbb{E}[U_k] = \mathbb{E}[\lim_{k \to \infty} U_k] \tag{13}$$

Finally, we have:

$$\lim_{k \to \infty} \mathbb{E}[U_k] = \mathbb{E}[W_0] - w_{\infty} \quad \text{and} \quad \mathbb{E}[\lim_{k \to \infty} U_k] = \mathbb{E}[W_0] - \mathbb{E}[W_{\infty}]$$
(14)

showing that  $\mathbb{E}[W_{\infty}] = w_{\infty}$  and concluding the proof of (ii). Moreover, using (11) we have that  $W_k \leq W_{k-1} - X_k$  which yields:

$$\sum_{j=1}^{\infty} X_j \le W_0 - W_{\infty} < \infty$$

$$\sum_{j=1}^{\infty} \mathbb{E}[X_j] \le \mathbb{E}[W_0] - w_{\infty} < \infty$$
(15)

which concludes the proof of the lemma.

#### 5.2. Proof of theorem 1

### 5.2.1. Proof of (I)

Set for all  $\vartheta \in \Theta$ ,  $i \in [N]$  and  $k \ge 1$ :

$$a_i^k(\vartheta) \triangleq f_{i,\theta^{\tau_{i,k}}}(\vartheta) \quad \text{and} \quad \bar{a}^k(\vartheta) = \sum_{i=1}^N a_i^k(\vartheta)$$
 (16)

where the function  $f_{i,\theta^{\tau_{i,k}}}$  is defined by (1) and  $\tau_{i,k}$  is defined recursively as follows:

$$\tau_{i,k} = k - 1$$
 if  $i \in I_k$  and  $\tau_{i,k} = \tau_{i,k-1}$  otherwise (17)

For any  $k \geq 1$  and  $\theta \in \Theta$  the following decomposition plays a key role:

$$\hat{a}^{k}(\vartheta) = \hat{a}^{k-1}(\vartheta) + \sum_{i \in I_{k}} \{\hat{f}_{i,\theta^{k-1}}(\vartheta) - \hat{a}_{i}^{k-1}(\vartheta)\}$$
(18)

where for all  $\vartheta \in \Theta$ ,  $i \in [N]$  and  $k \ge 1$ :

$$\hat{a}_{i}^{k}(\vartheta) \triangleq \hat{f}_{i,\theta^{\tau_{i,k}}}(\vartheta) \quad \text{and} \quad \hat{a}^{k}(\vartheta) = \sum_{i=1}^{N} \hat{a}_{i}^{k}(\vartheta)$$
 (19)

Set the following notations:

$$\begin{split} V_k &\triangleq \bar{a}^k(\theta^k), \\ X_k &\triangleq -\sum_{i \in I_k} \{f_{i,\theta^{k-1}}(\theta^{k-1}) - a_i^{k-1}(\theta^{k-1})\}, \\ E_k &\triangleq \sum_{i \in I_k} \{\hat{f}_{i,\theta^{k-1}}(\theta^{k-1}) - f_{i,\theta^{k-1}}(\theta^{k-1})\} \\ &+ \sum_{i \in I_k} \{a_i^{k-1}(\theta^{k-1}) - \hat{a}_i^{k-1}(\theta^{k-1})\} \\ &+ \bar{a}^k(\theta^k) - \hat{a}^k(\theta^k) + \hat{a}^{k-1}(\theta^{k-1}) - \bar{a}^{k-1}(\theta^{k-1}). \end{split}$$

Combining (18) with  $\bar{a}^k(\theta^k) = \bar{a}^k(\theta^k) - \hat{a}^k(\theta^k) + \hat{a}^k(\theta^k)$  and  $\hat{a}^k(\theta^k) \leq \hat{a}^k(\theta^{k-1})$ , we obtain:

$$V_k \le V_{k-1} - X_k + E_k. (20)$$

where  $a_i^{k-1}$  and  $\bar{a}^k$  are defined in (16). We now check the assumptions of Lemma 1. Note first that the sequence  $(V_k)_{k\geq 0}$  is bounded from below under assumption M 1. We now check that  $X_k \geq 0$  thanks to the following relation obtained using the definition of surrogate functions:

$$X_k = \sum_{i \in I_k} \{ a_i^{k-1}(\theta^{k-1}) - f_{i,\theta^{k-1}}(\theta^{k-1}) \} = \sum_{i \in I_k} \{ a_i^{k-1}(\theta^{k-1}) - f_i(\theta^{k-1}) \} \ge 0.$$
 (21)

We finally have to prove the convergence of the series  $\sum_{k=0}^{\infty} \mathbb{E}[|E_k|]$ . For this purpose, we will show that for all  $i \in [N]$ :

$$\sum_{k=0}^{\infty} \mathbb{E}\left[|\hat{a}_i^k(\theta^k) - a_i^k(\theta^k)|\right] < \infty \tag{22}$$

We have, using the Tower property of the conditional expectation and the Jensen inequality:

$$\mathbb{E}\Big[|\hat{a}_i^k(\theta^k) - a_i^k(\theta^k)|\Big] \le \mathbb{E}\Big[\mathbb{E}_{i,\theta^{\tau_{i,k}}} \left[\sup_{\vartheta \in \Theta} |\hat{a}_i^k(\vartheta) - a_i^k(\vartheta)|\right]\Big]$$
(23)

Under assumption M 3 applied with the function  $\vartheta \to \hat{a}_i^k(\vartheta)$ , for all  $i \in [N]$  we have:

$$\mathbb{E}_{i,\theta^{\tau_{i,k}}} \left[ \sup_{\vartheta \in \Theta} |\hat{a}_i^k(\vartheta) - a_i^k(\vartheta)| \right] \le C_i(r_{i,\theta^{\tau_{i,k}}}) M_{\tau_{i,k}}^{-1/2}$$
(24)

where  $C_i(r_{i,\theta^{\tau_{i,k}}})$  is a finite constant defined by (3) and  $\tau_{i,k}$  is defined by (17).

Thus, we have that:

$$\mathbb{E}\Big[\big|\hat{a}_i^k(\theta^k) - a_i^k(\theta^k)\big|\Big] \le C_i(r_{i,\theta^{\tau_{i,k}}}) \mathbb{E}[M_{\tau_{i,k}}^{-1/2}] \tag{25}$$

Since, any index i is included in a mini-batch with a probability equal to  $\frac{p}{N}$  conditionally independently from the past, we obtain that:

$$\mathbb{E}[M_{\tau_{i,k}}^{-1/2}] = \sum_{j=1}^{k} \left(1 - \frac{p}{N}\right)^{j-1} \frac{p}{N} M_{k-j}^{-1/2}$$
(26)

Taking the infinite sum of this term yields:

$$\sum_{k=1}^{\infty} \mathbb{E}[M_{\tau_{i,k}}^{-1/2}] = \sum_{k=1}^{\infty} \sum_{j=1}^{k} \left(1 - \frac{p}{N}\right)^{j-1} \frac{p}{N} M_{k-j}^{-1/2} 
= \sum_{k=1}^{\infty} \sum_{l=0}^{\infty} \left(1 - \frac{p}{N}\right)^{k-(l+1)} \frac{p}{N} \mathbb{1}_{\{l \le k-1\}} M_l^{-1/2} 
= \frac{p}{N} \sum_{l=0}^{\infty} \left(1 - \frac{p}{N}\right)^{-(l+1)} M_l^{-1/2} \sum_{k=l+1}^{\infty} \left(1 - \frac{p}{N}\right)^k 
= \sum_{l=0}^{\infty} M_l^{-1/2}$$
(27)

which proves identity (22), using assumption M 4. By summing over the indices  $i \in [N]$ , (22) implies:

$$\sum_{k=0}^{\infty} \mathbb{E}\left[|\hat{a}^k(\theta^k) - \bar{a}^k(\theta^k)|\right] < \infty \tag{28}$$

Hence, we obtain that  $\sum_{k=0}^{\infty} |\hat{a}^k(\theta^k) - \bar{a}^k(\theta^k)| < \infty$  almost surely which implies that:

$$\lim_{k \to \infty} \hat{a}^k(\theta^k) - \bar{a}^k(\theta^k) = 0 \quad \text{a.s.}$$
 (29)

Similarly, using assumption M 3 applied for all  $i \in [N]$ , with the function  $\vartheta \to \nabla \hat{a}_i^k(\vartheta)$  we obtain:

$$\lim_{k \to \infty} \nabla \hat{a}^k(\theta^k) - \nabla \bar{a}^k(\theta^k) = 0 \quad \text{a.s.}$$
 (30)

It follows from (22) and (28) that  $\sum_{k=0}^{\infty} \mathbb{E}[|E_k|] < \infty$  and that the series  $\sum_{k=0}^{\infty} \epsilon_k$  converges to an almost surely finite limit. Hence by Lemma 1 and (29) we get:

- the sequence  $(\bar{a}^k(\theta^k))_{k>0}$  and the series  $\sum_{k=0}^{\infty} \chi_k$  converge a.s.
- the sequence  $(\mathbb{E}\left[\bar{a}^k(\theta^k)\right])_{k\geq 0}$  and the series  $\sum_{k=0}^{\infty}\mathbb{E}\left[X_k\right]$  converge with  $\lim_{k\to\infty}\mathbb{E}\left[\bar{a}^k(\theta^k)\right] = \mathbb{E}\left[\lim_{k\to\infty}\bar{a}^k(\theta^k)\right]$ .
- the sequence  $(\hat{a}^k(\theta^k))_{k\geq 0}$  converges a.s. and the sequence  $(\mathbb{E}[\hat{a}^k(\theta^k)])_{k\geq 0}$  converges.

Now, we have to prove the almost-sure convergence of the sequence  $(f(\theta^k))_{k\geq 0}$  and the convergence of  $(\mathbb{E}[f(\theta^k)])_{k\geq 0}$ .

Let us denote for all  $\theta \in \Theta$  and a subset  $J \subset [N]$ :

$$f_{J}(\theta) \triangleq \sum_{i \in J} f_{i}(\theta)$$

$$a_{J}^{k-1}(\theta) \triangleq \sum_{i \in J} a_{i}^{k-1}(\theta)$$
(31)

The Beppo-Levi theorem and the Tower property of the conditional expectation imply:

$$\mathsf{M} \triangleq \mathbb{E}\left[\sum_{k=1}^{\infty} X_{k}\right] = \sum_{k=0}^{\infty} \mathbb{E}\left[a_{I_{k}}^{k-1}(\theta^{k-1}) - f_{I_{k}}(\theta^{k-1})\right]$$
$$= \sum_{k=0}^{\infty} \mathbb{E}\left[\mathbb{E}\left[a_{I_{k}}^{k-1}(\theta^{k-1}) - f_{I_{k}}(\theta^{k-1}) \middle| \mathcal{F}_{k-1}\right]\right]$$
(32)

with  $\mathbb{E}\left[f_{I_k}(\theta^{k-1}) \middle| \mathcal{F}_{k-1}\right] = \frac{p}{N} f(\theta^{k-1})$  and  $\mathbb{E}\left[\left[a_{I_k}^{k-1}(\theta^{k-1})\middle| \mathcal{F}_{k-1}\right] = \frac{p}{N} \sum_{i=1}^N a_i^{k-1}(\theta^{k-1}) = \frac{p}{N} \bar{a}^{k-1}(\theta^{k-1})$  where  $\mathcal{F}_{k-1} = \sigma(I_j, j \leq k-1)$  is the filtration generated by the sampling of the indices. We thus obtain:

$$\mathsf{M} = \frac{p}{N} \sum_{k=0}^{\infty} \mathbb{E} \left[ \bar{a}^{k-1}(\theta^{k-1}) - f(\theta^{k-1}) \right] = \frac{p}{N} \mathbb{E} \left[ \sum_{k=0}^{\infty} \bar{a}^{k-1}(\theta^{k-1}) - f(\theta^{k-1}) \right] < \infty$$
 (33)

which yields to:

$$\mathbb{E}\left[\sum_{k=1}^{\infty} X_k\right] = \frac{p}{N} \mathbb{E}\left[\sum_{k=1}^{\infty} \{\bar{a}^{k-1}(\theta^{k-1}) - f(\theta^{k-1})\}\right] < \infty$$
 (34)

showing that:

$$\lim_{k \to \infty} \mathbb{E} \left[ \bar{a}^k(\theta^k) - f(\theta^k) \right] = 0$$

$$\lim_{k \to \infty} \bar{a}^k(\theta^k) - f(\theta^k) = 0 \quad \text{a.s.}$$
(35)

showing that the sequence  $\left(\mathbb{E}\left[f(\theta^k)\right]\right)_{k\geq 0}$  converges and that  $\left(f(\theta^k)\right)_{k>0}$  converges a.s.

#### 5.2.2. Proof of (II)

Let us define, for all  $k \geq 0$ ,  $\bar{h}_k$  as:

$$\bar{h}^k: \vartheta \to \sum_{i=1}^N a_i^k(\vartheta) - f_i(\vartheta)$$
 (36)

 $\bar{h}^k$  is L-smooth with  $L = \sum_{i=1}^N L_i$  since each of its component is  $L_i$ -smooth by definition of the surrogate functions. Using the particular parameter  $\vartheta^k = \theta^k - \frac{1}{L} \nabla \bar{h}_k(\theta^k)$  we have the following classical inequality for smooth functions (cf. Lemma 1.2.3 in (Nesterov, 2007)):

$$0 \leq \bar{h}^k(\vartheta^k) \leq \bar{h}^k(\theta^k) - \frac{1}{2L} \|\nabla \bar{h}^k(\theta^k)\|_2^2$$

$$\Longrightarrow \|\nabla \bar{h}^k(\theta^k)\|_2^2 \leq 2L\bar{h}^k(\theta^k)$$
(37)

Using (35), we conclude that  $\lim_{k\to\infty} \|\nabla \bar{h}^k(\theta^k)\|_2 = 0$  a.s. Then, the decomposition of  $\langle \nabla f(\theta^k), \theta - \theta^k \rangle$  for any  $\theta \in \Theta$  yields:

$$\langle \nabla f(\theta^k), \theta - \theta^k \rangle = \langle \nabla \bar{a}^k(\theta^k), \theta - \theta^k \rangle - \langle \nabla \bar{h}^k(\theta^k), \theta - \theta^k \rangle$$

$$= \langle \nabla \bar{a}^k(\theta^k) - \nabla \hat{a}^k(\theta^k), \theta - \theta^k \rangle + \langle \nabla \hat{a}^k(\theta^k), \theta - \theta^k \rangle - \langle \nabla \bar{h}^k(\theta^k), \theta - \theta^k \rangle$$
(38)

Note that  $\theta^k$  is the result of the minimization of  $\hat{a}^k(\theta)$  on the constrained set  $\Theta$ , therefore for all  $\theta \in \Theta$ ,  $\langle \nabla \hat{a}^k(\theta^k), \theta - \theta^k \rangle \geq 0$ . Thus, we obtain, using the Cauchy-Schwarz inequality:

$$\langle \nabla f(\theta^k), \theta - \theta^k \rangle \ge \langle \nabla \bar{a}^k(\theta^k) - \nabla \hat{a}^k(\theta^k), \theta - \theta^k \rangle - \langle \nabla \bar{h}^k(\theta^k), \theta - \theta^k \rangle \ge -\|\nabla \bar{a}^k(\theta^k) - \nabla \hat{a}^k(\theta^k)\|_2 \|\theta - \theta^k\|_2 - \|\nabla \bar{h}^k(\theta^k)\|_2 \|\theta - \theta^k\|_2$$
(39)

By minimizing over  $\Theta$  and taking the infimum limit, we get, using (30):

$$\lim \inf_{k \to \infty} \inf_{\theta \in \Theta} \frac{\langle \nabla f(\theta^k), \theta - \theta^k \rangle}{\|\theta - \theta^k\|_2} \ge -\lim_{k \to \infty} \left( \|\nabla \bar{a}^k(\theta^k) - \nabla \hat{a}^k(\theta^k)\|_2 + \|\nabla \bar{h}^k(\theta^k)\|_2 \right) = 0 \quad (40)$$

which is the Asymptotic Stationary Point Condition (ASPC).
